

1. In the GameHandler class, there were a lot of methods for doing stuff like showing the pause overlay, running the game, and showing the end game screen. We created a new class for the Pause overlay so instead of having all of the pause overlay methods for when ESC is pressed in the GameHandler class, we made a new class for it to shorten the God Class GameHandler. Pressing ESC now delegates to this new class, which is responsible for showing and hiding the pause menu.
2. In the UiHandle class, for the render method, we created a separate method called drawAll, this helps simplify the render class from clutter. The render method in UiHandle was doing too much (drawing the map, entities, HUD, etc.).
3. In the GameObject class we removed the setters, as they were just useless code - never being called anywhere in the codebase.
4. In the Player class, we removed the OnCollide method as it was useless code, and was implemented in a separate dedicated collision handler class. We removed this method to avoid duplication of responsibilities and keep collision logic in a single place.
5. The Main class previously contained low level button styling logic, which cluttered the class. Added a separate class for button styler so that the main class has less clutter, increasing the cohesion. Main now uses this instead, resulting in higher cohesion and a clearer separation between application setup and UI component details.
6. The Main class previously contained low level code blocks for constructing buttons, which cluttered the class. Added a separate class for making buttons, and is passed into the main class. Now the main class has less clutter, increasing the cohesion. Main now uses this instead, resulting in higher cohesion and a clearer separation between application setup and UI components.
7. In the Draw Entity class, we introduced a dedicated method to remove the entity layer from the stage. Previously, this behavior was implicit and

scattered. Centralizing it in a single method improves readability and makes the intention of the entity layer explicit.

8. Created a separate method called `drawMap` to remove the burden from the render method, further enhancing cohesion.
